# Opportunities, risks and tasks

## Versions

**High importance for repeatability**

A result refers only to the current inventory. Corrections, new books or other extractions can change the research basis.

**How does Git help?** Commit and release identifiers allow accurate assignment. An archive keeps the designated data regardless of the current host.

**Concerns:** Which selection and which tool holder were used? Is the exact version obtained?

**Action:** Connect release, version archive, selection and procedures in an analysis manifest.

**Responsible for:** Researchers and Release Managers

## Data loss

**High importance for data quality**

The analysis is running, although a transformation has lost separate solutions. Just properties that the own script does not use remain slightly ignored.

**How does Git help?** Comparisons and designated tool stands limit the loss. Regression tests make known cases repeatable verifiable.

**Concerns:** Do we only examine the properties of our current research question or the existing collection and other ways of using it?

**Action:** Compare inventory before and after processing, read purposefully and document the correction in the release.

**Responsible for:** Lea, Jonas and technical editors

## Follow-up research

**Scientific opportunity with additional care needs**

External researchers bring with them books, corrections and new annotations. This expands the corpus and its questions; testing and supervision remain work.

**How does Git help?** Pull/merge requests and related repos make contributions and derivatives comprehensible.

**Concerns:** Who checks and maintains the extension? Are common anchors and version relations agreed?

**Action:** Curate contributions by capacity; consciously connect external layers or partial corpora.

**Responsible for:** Project management, maintainers and contributors

## Maintenance

**High importance for continuity**

Lea's temporary job ends. A second account does not prevent release knowledge or maintenance time from missing.

**How does Git help?** Versioned instructions, tests and clear data levels facilitate handovers; working time must be institutionally secured.

**Concerns:** Can another person check, derive and create a sample release?

**Action:** Perform handover test, name roles and scope of care.

**Responsible for:** Chair, technical representation and institution

## Local use

**Opportunity for range and ongoing operational obligation**

An application can open up new uses. It needs a service beyond the data publication.

**How does Git help?** Separate software versions hold development and data levels assigned. Hosting and support do not arise automatically.

**Concerns:** Which need justifies which technology?

**Action:** TEI and offer exports reliably; provide additional services only with carriership.

**Responsible for:** Project management and infrastructure promoters

## Host Change

**Continuity needs more than one mirror**

Git data remains transferable, platform operations and automation may be missing.

**How does Git help?** Git transfers objects and references. Platform information and procedures must be consciously exported or documented.

**Concerns:** What else can be found and executable after the change?

**Action:** Check archived releases and rebuild on other infrastructure.

**Responsible for:** Institutional owners and archive holders

## Entry

**High importance for actual use**

A public repo can remain incomprehensible: several last versions, large packages, local paths and unclear annotations prevent the first investigation.

**How does Git help?** README, publication concept, small examples and named releases can be versioned together. Issues collect concrete feedback.

**Concerns:** Can anyone recognize the decisive structure and begin without personal introduction?

**Action:** Test entry with a foreign environment and provide a small complete examination.

**Responsible for:** Lea and the editorial staff

## markup

**Differences can distort analyses unnoticed**

Partial stocks use different rules or automatically generated annotations without detectable test status. An identical search pattern does not capture the same thing everywhere.

**How does Git help?** Versioned rules, tests and documented transformations explain differences. New annotations can be connected as designated layers.

**Concerns:** Which practice applies in which inventory? Which annotation is automatic and how has it been tested?

**Action:** Document markup practices, check differences and identify unified exports as derivatives.

**Responsible for:** Model managers and annotation creators
